Exciting times of high precision measurements

Spectroscopy: ESO's ESPRESSO: 10 cm/s stability

Transmission spectroscopy: JWST: 10 ppm

Exciting times of high precision measurements

Transmission spectroscopy: JWST: 10 ppm

Reality: limiting factor for exoplanet detection are not instrumental capabilities, but the stellar activity signal

Session: Stellar Activity as a Limiting Factor for Characterising Exoplanets

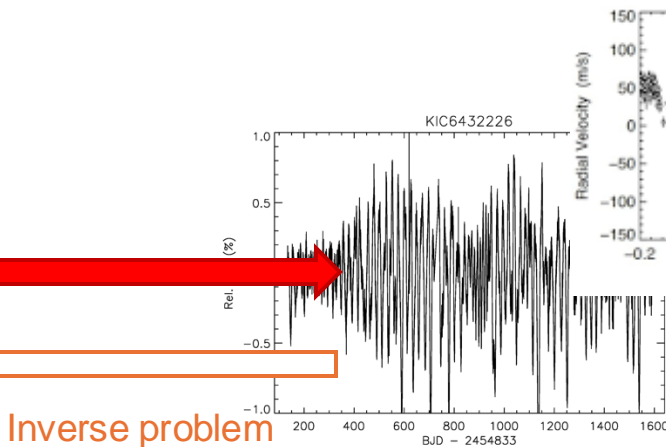

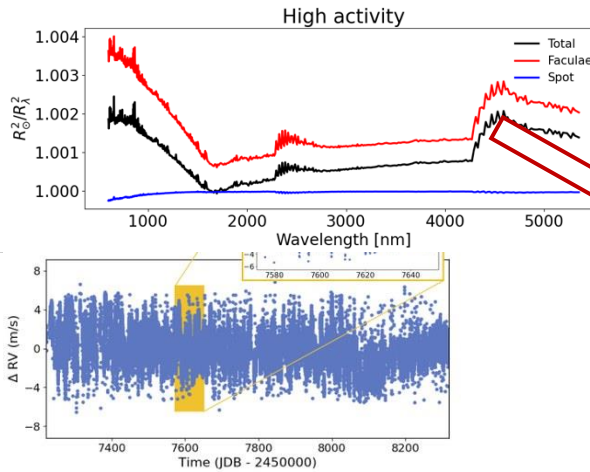

Spectroscopy: ESO's ESPRESSO: 10 cm/s stability

Stellar activity conundrum

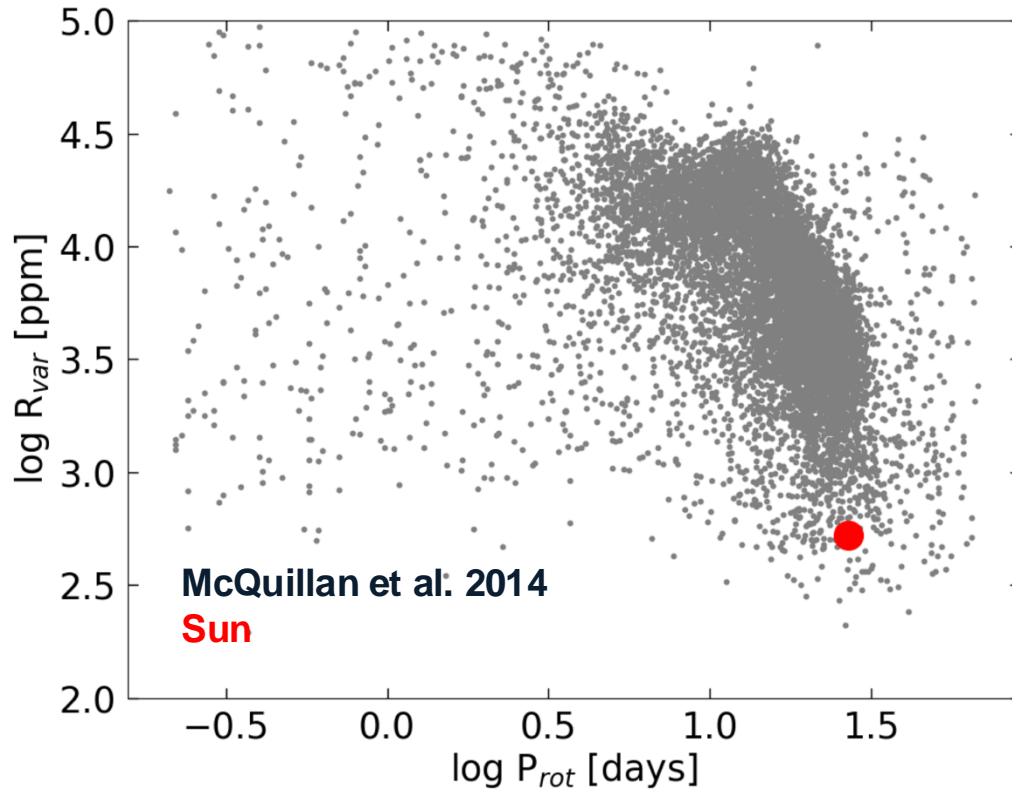

Inverse problem generally ill-posed

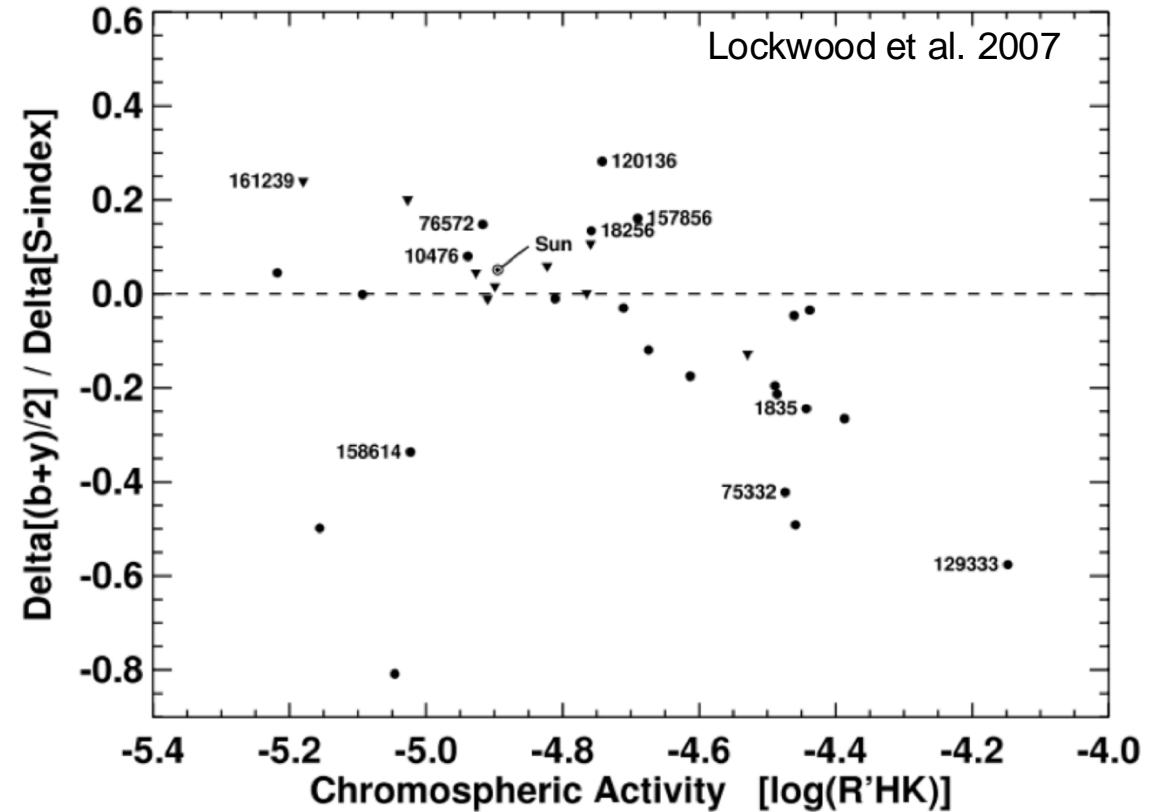

Inverse problem generally ill-posed

Explaining observed patterns in stellar variability on different timescales

Kepler: rotational timescale

Strömgren b+y and Ca II H&K: decadal/cycle timescale

SATIRE

$$\Delta S_{\text{tot}}(t) = \Delta S_{\text{spots}}(t) + \Delta S_{\text{faculae}}(t)$$

Synthetic lightcurves of a star with solar like distribution of magnetic features as seen by *Kepler*

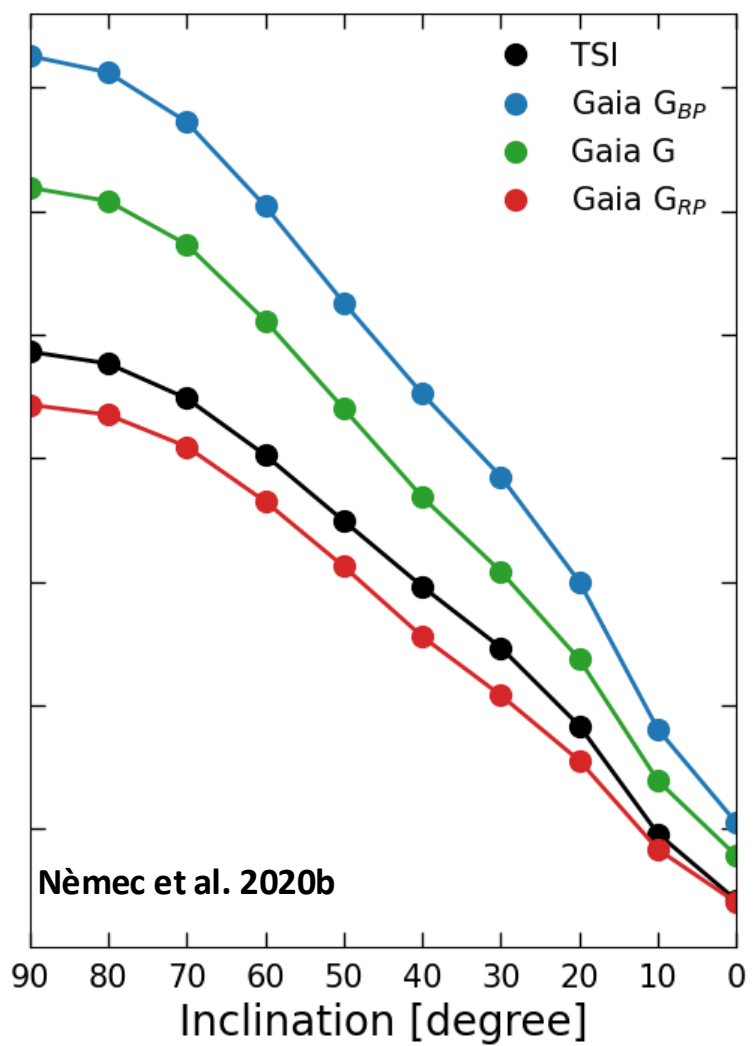

Nèmec et al. 2020b

Equatorial bound observer: transit + evolution of magnetic features

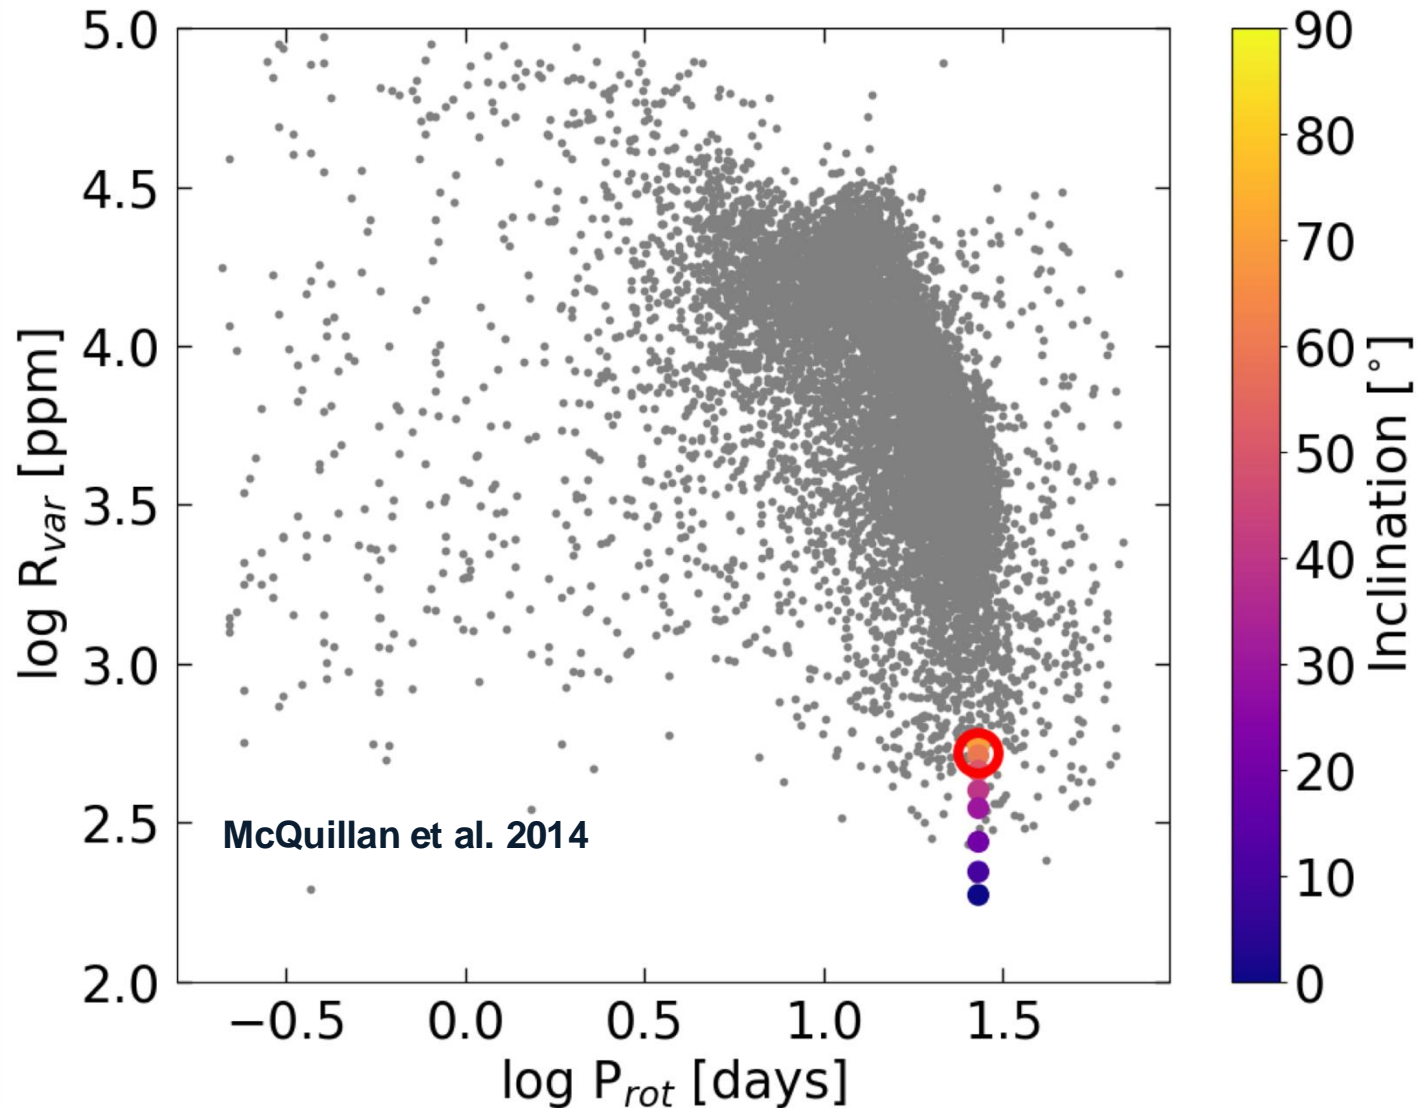

Pole bound observer: evolution of magnetic features

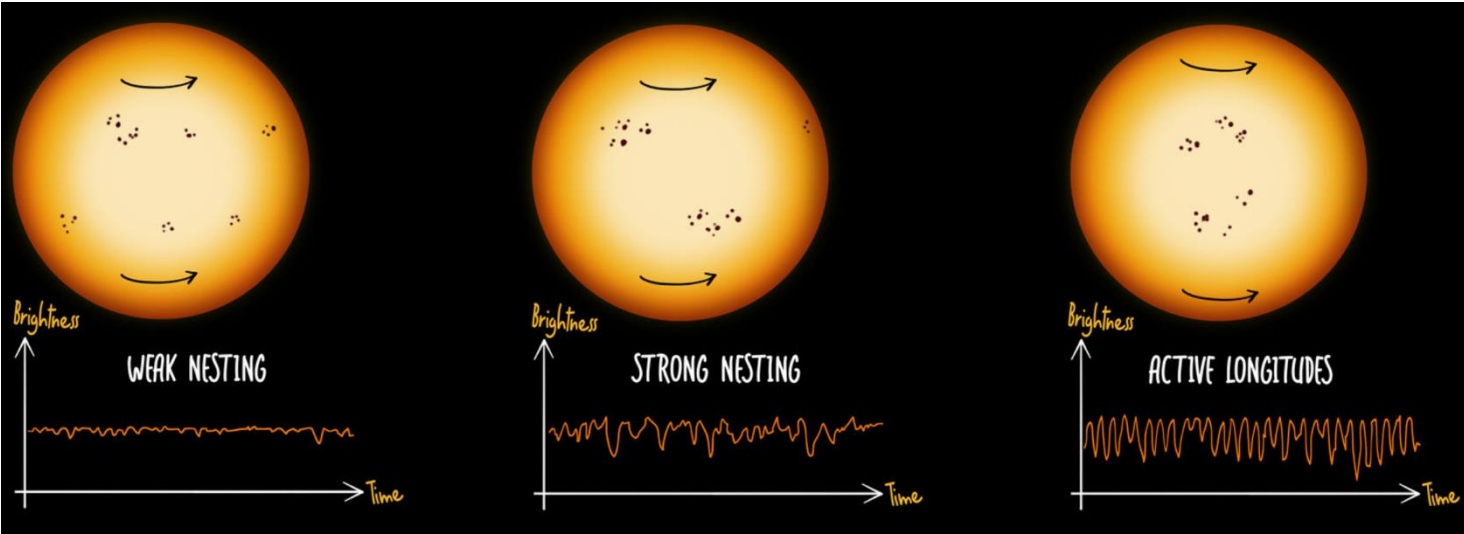

Nèmec et al. 2020b

- Visibility of magnetic features strongly depends on the passband
- On average, out-of-ecliptic observers will observe 15% less variability

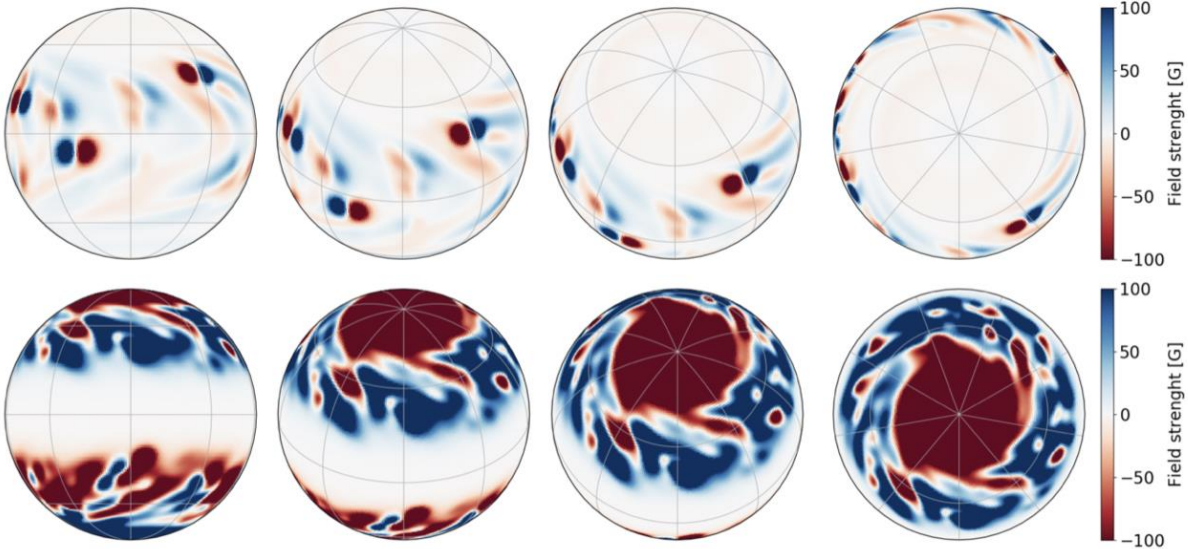

Reinhold et al. (2020): stars with detected near-solar rotation periods show more regular LCs

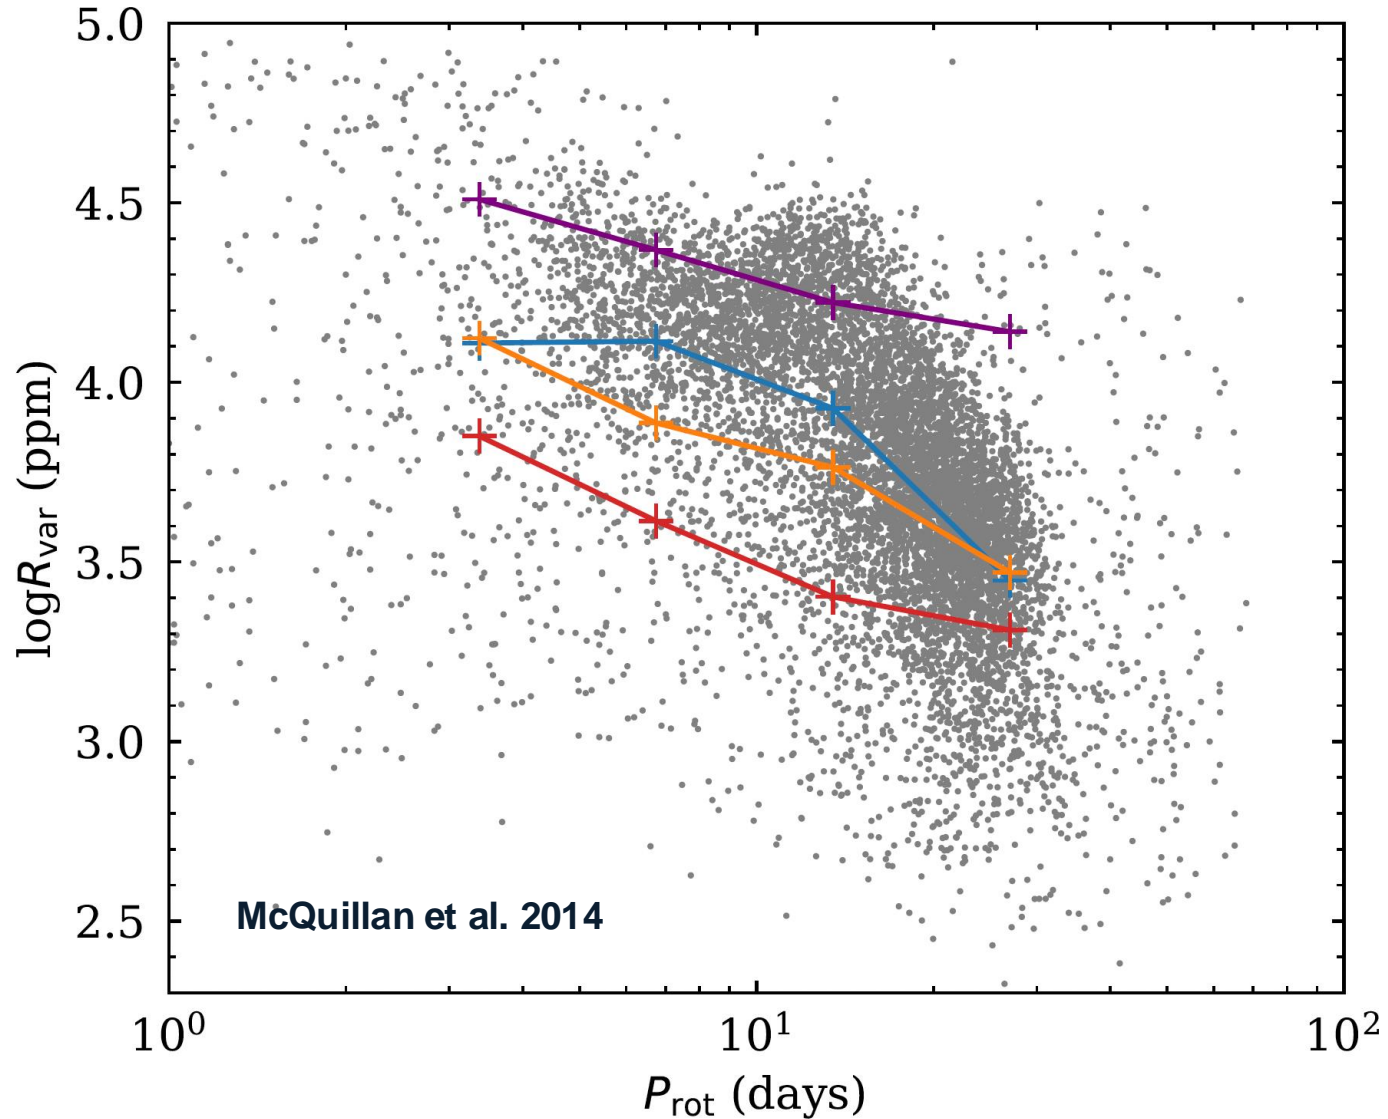

Isik et al. (ApJ, 2020): higher amplitude of variability and regularity can be explained by nesting of regions for solar rotators

Nèmec et al. (2023): Extended the nesting approach to faster rotators using the Surface Flux Transport Model

Somwya, Nèmec, et al. 2022

Dependence of rotational variability on the rotation period can be explained by increasing nesting of active regions

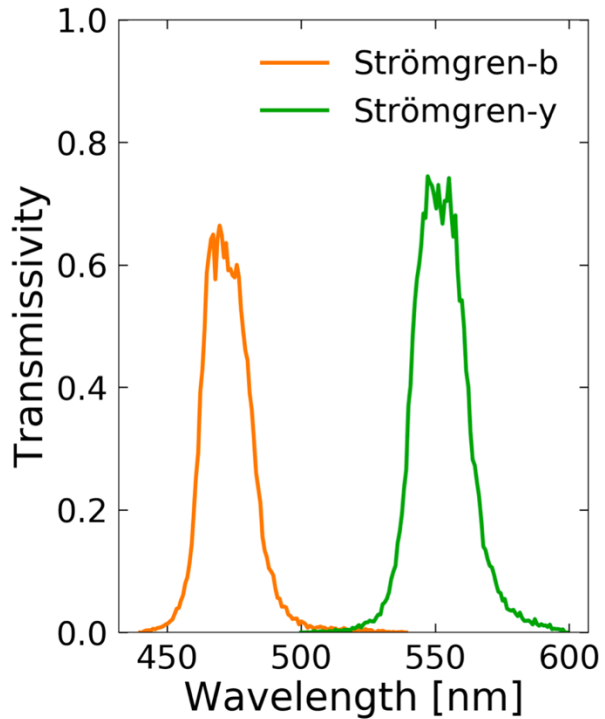

Long term monitoring

Photometry

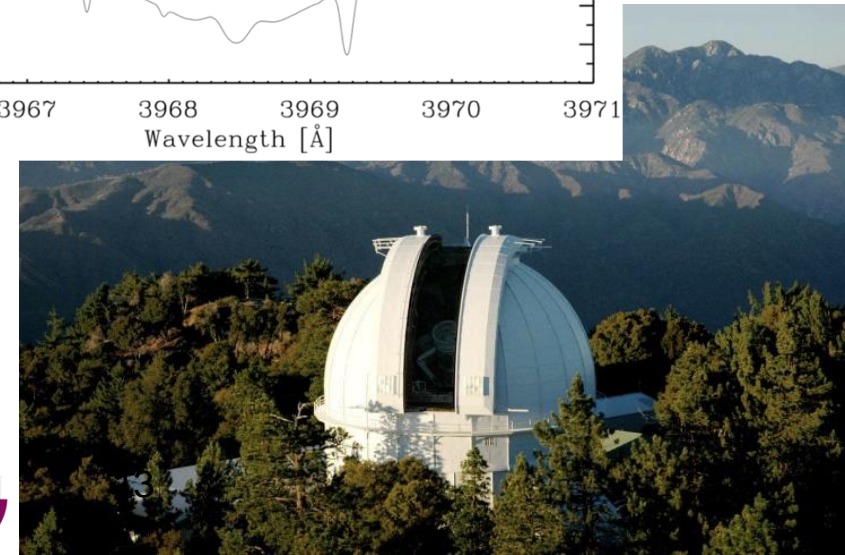

Lowell Observatory

Calcium II H&K

Mount Wilson observatory

Lockwood et al. 2007

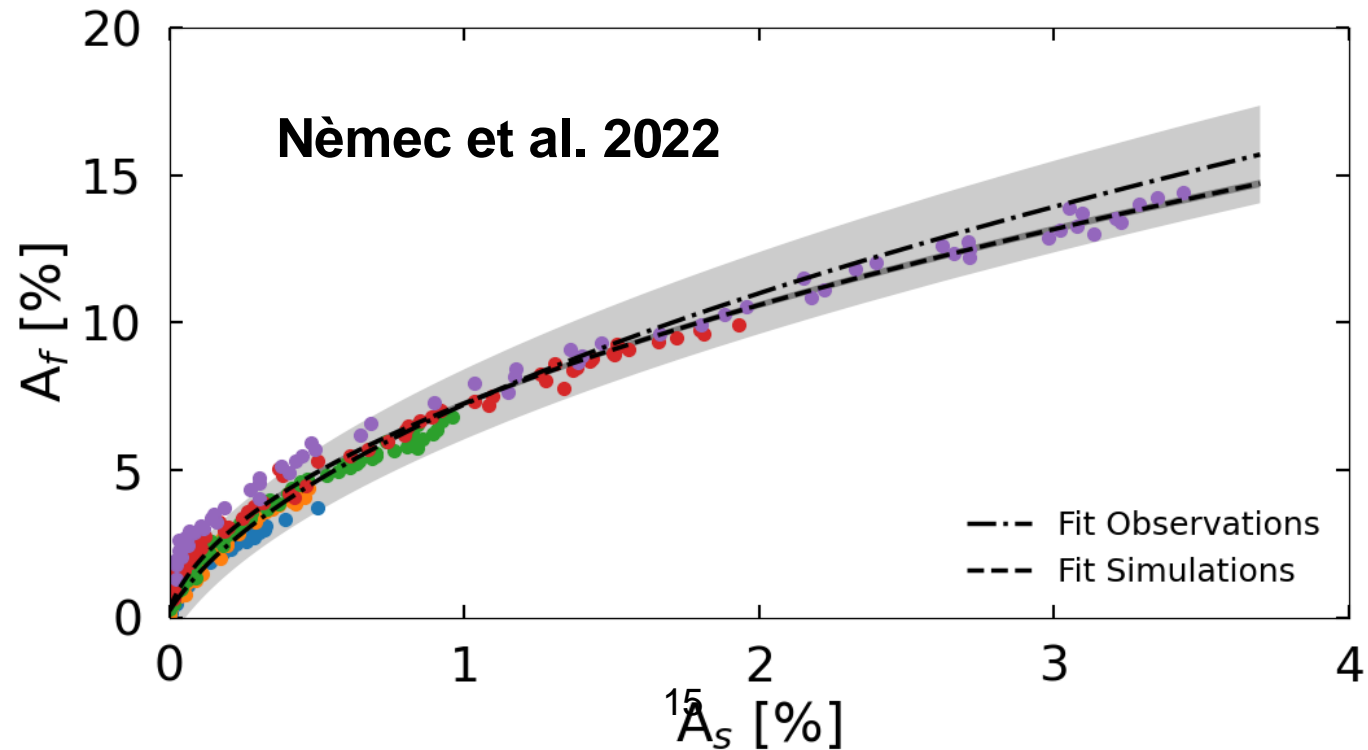

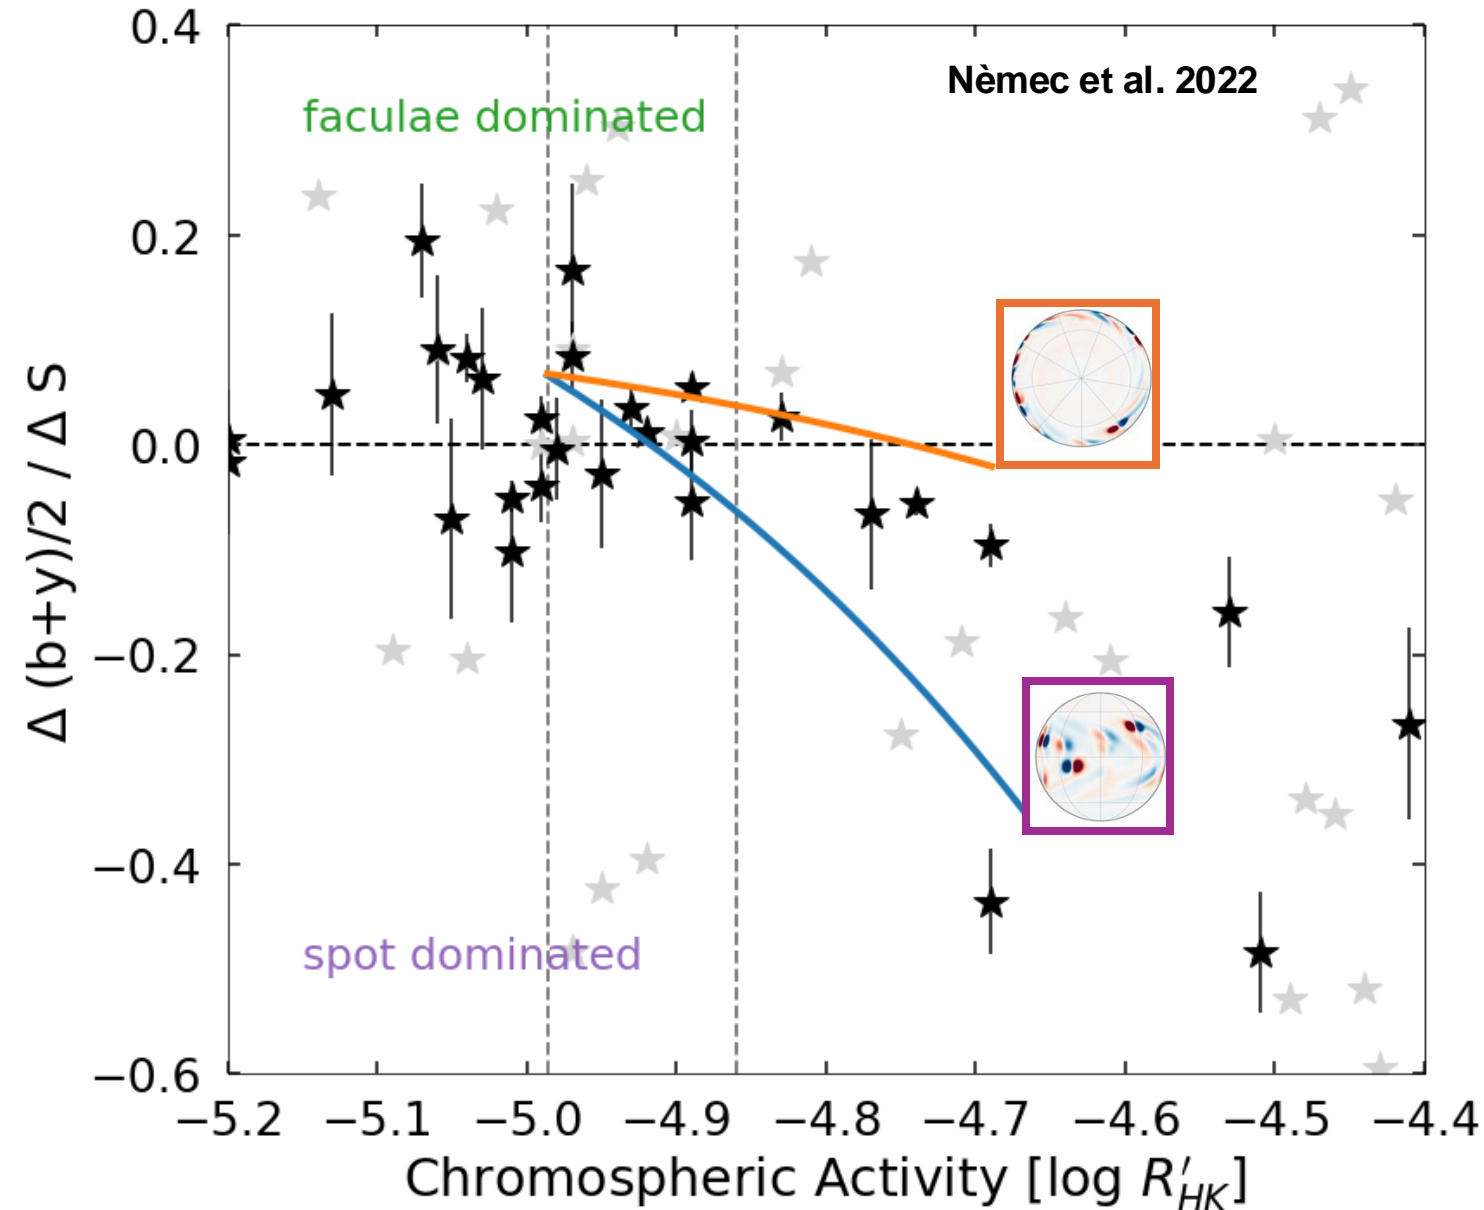

Model explains solar data and indicates that solar dependence can be extrapolated to more active stars

Hint, what causes the transition from faculae to spot dominated, is already in the solar data

Model captures the area, at which the transition occurs very well

Most importantly: a simple relationship between S-index and spot/faculae is valid!

Summary

- Sun is the proxy of (Sun-like) stellar variability
- Rotational timescale
 - Active region distribution needs to be altered to explain the observed variability distribution
 - with increasing rotation rate, nesting degree needs to be increased
- Cycle timescale
 - Small scale flux cancels out on active stars, leading to the switch from faculae to spot dominated on the stellar activity cycle timescale
